Algorithmic Paradigms

程序代写代做 CS 编程辅导

- General approaches to the construction of *correct* and *efficient* solutions to problems
- Such methods are called *paradigms* because:
 - They provide templates suited to solving a broad range of diverse problems.
 - They can be translated into common control and data structures provided by most high-level languages.
 - The temporal and spatial requirements of the algorithms can be precisely analyzed.
- Although more than one technique may be applicable to a specific problem, it is often the case that an algorithm constructed by one approach is clearly superior to equivalent solutions built using alternative techniques.

Complete search

程序代写代做 CS 编程辅导

- Also know (related) as recursive backtracking or brute force.

- Backtracking is a sort of exhaustive search or brute force
- It is a method for solving a problem by searching (up to) the entire search space to obtain the required solution.

• The search space can be large but finite.

WeChat: cstutorcs

- Does not exist an algorithm that uses a method other than exhaustive search.

Assignment Project Exam Help

- Need for developing techniques of searching, with the hope of cutting down the search space to possibly a much smaller space. Backtracking can be described as an organized exhaustive search which often avoids searching all possibilities.

Email: tutorcs@163.com

QQ: 749389476

<https://tutorcs.com>

Recursive Backtracking – example

程序代写代做 CS 编程辅导

- Problem: In chess (with a standard 8x8 board), it is possible to place eight queens on a board so that no queen can be taken by any other. Write a program that will determine all such possible arrangements.

WeChat: cstutorcs

Recursive Backtracking – example

程序代写代做 CS 编程辅导

- Solution 1:

- Use a solution vector s where $s[i]$ is true iff there is a queen on the i^{th} square.
- There are $2^{64} \approx 1.84 \times 10^{19}$ different true/false vectors for 8X8 board.

WeChat: cstutorcs

Assignment Project Exam Help

- Solution 2:

- Have the i^{th} element of a solution vector explicitly list the square where the i^{th} queen resides. a_i will be an integer from 1 to n^2 .
- There are $64^8 \approx 2.81 \times 10^{14}$ vectors.

Email: tutorcs@163.com
QQ: 749389476

<https://tutorcs.com>

Recursive Backtracking – example

程序代写代做 CS 编程辅导

- Solution 3:

- Prune solution 2 by removing symmetries. Ensure that the queen in a_i sits on a higher number than the queen in a_{i-1}
- How many ways can we choose k things from a set of n items?
 - In this case there are 64 squares and we want to choose 8 of them to put queens on.

WeChat: cstutorcs

$$\binom{n}{k} = \frac{n \cdot (n-1) \cdots (n-k+1)}{k \cdot (k-1) \cdots (k-(k-1))} = \frac{n!}{(n-k)!} \text{ if } 0 \leq k \leq n$$

- This change will reduce the search space to $\binom{64}{8} = 4.426 \times 10^9$
- Includes lots of set ups with multiple queens in the same column.

QQ: 749389476

<https://tutorcs.com>

Recursive Backtracking – example

程序代写代做 CS 编程辅导

- Solution 4:

- Note that there must be one queen per column for a n-queens solution. Then you can generate candidates of the i^{th} queen to the eight squares on the i^{th} column.
- There are $8^8 \approx 1.67 \times 10^7$ vectors for 8X8 board.

WeChat: cstutorcs

Assignment Project Exam Help

- Solution 5:

- Since no two queens can share the row or column, we know that the n columns of a complete solution must form a permutation of n .
- We reduce then our search space to just $8! = 40320$ vectors.

QQ: 749389476

<https://tutorcs.com>

Recursive Backtracking – example

程序代写代做 CS 编程辅导

- Solution 6:

- You can improve solution 6 by knowing that no two queens can share any of the two diagonals.

WeChat: cstutorcs

- Solution 7:

- Identify the 12 unique (or fundamental) solutions. You can utilize this fact by only generating the 12 unique solutions and, if needed, generate the whole 92 by rotating and reflecting these 12 unique solutions

Email: tutorcs@163.com
QQ: 749389476

<https://tutorcs.com>

Recursive Backtracking – Solution 4

程序代写代做 CS编程辅导

- Solution 4:

- There are $8^8 \approx 1.67 \times 10^8$ ways to place 8 queens on an 8X8 board.
- If number of queens is greater than 8, we can immediately realize there can't be more than one queen per column. I can iterate through all the possible rows for each column.

```
for(int r0 = 0; r0 < 8; r0++) {  
    board[r0][0] = 'q';  
    for(int r1 = 0; r1 < 8; r1++) {  
        board[r1][1] = 'q';  
        for(int r2 = 0; r2 < 8; r2++) {  
            board[r2][2] = 'q';  
            // a little later  
            for(int r7 = 0; r7 < 8; r7++) {  
                board[r7][7] = 'q';  
                if( queensAreSafe(board) )  
                    printSolution(board);  
                board[r7][7] = ' '; //pick up queen  
            }  
            board[r6][6] = ' '; // pick up queen
```

Recursive Backtracking – Solution 4

程序代写代做 CS 编程辅导

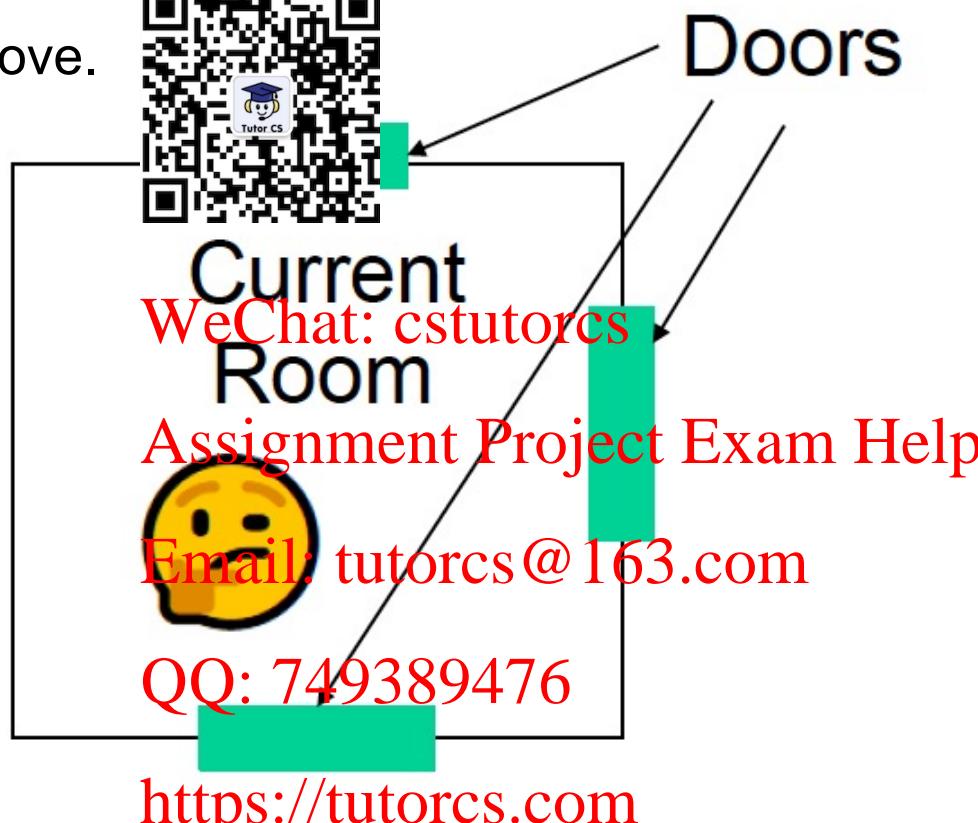

- What about if you do not have 8, but N queens:
 - You do not know how many loops to write.
- Do the problem recursively using backtracking.
 - Recursive because later versions of the problem are just slightly simpler versions of the original.
 - You have $n - i$ queens to add.
 - Backtracking because we may have to try different alternatives.
 - Problem space consists of states (nodes) [chess board] and actions (paths that lead to new states) [placing a queen]
 - If a node only leads to failure go back to its "parent" node. Try other alternatives

Recursive Backtracking

Recursive Backtracing - Conclusions

程序代写代做 CS 编程辅导

- Generating versus Filtering:

- Programs that generate candidate solutions and then choose the ones that are correct ‘filters’ - recall the naive 8-queens solvers.
- Those that hone in exactly to the correct answer without any false starts are called ‘generators’ – recall the improved 8-queens solver with 12 solutions.
- Generally, filters are easier to code but run slower. Do the math to see if a filter is good enough

WeChat: cstutorcs

Assignment Project Exam Help

- Prune Infeasible Search Space Early:

Email: tutorcs@163.com

- Utilize Symmetries.

- In the 8-queens problem, there are 92 solutions but there are only 12 unique (or fundamental) solutions as there are rotations and reflections symmetries in this problem. You can utilize this fact by only generating the 12 unique solutions and, if needed, generate the whole 92 by rotating and reflecting these 12 unique solutions.

QQ: 749389476

<https://tutorcs.com>

Recursive Backtracing - Conclusions

程序代写代做 CS 编程辅导

- Backtracking algorithms are commonly used to make a sequence of decisions, with the goal of finding a recursively defined structure satisfying certain constraints.
 - In the n-queens problem, the goal is a sequence of queen positions, one in each row, such that no two queens attack each other. For each row, the algorithm decides where to place the queen.
- In each recursive call to the backtracking algorithm, we need to make exactly one decision, and our choice must be consistent with all previous decisions.
 - For the n-queens problem, we must pass in not only the number of empty rows, but the positions of all previously placed queens.
 - Finally, once we've figured out what recursive problem we really need to solve, we solve that problem by recursive brute force:
 - Try all possibilities for the next decision that are consistent with past decisions, and let the recursion worry about the rest.

Assignment Project Exam Help

Taken from
<https://www.explainxkcd.com>

Recursive Backtracking + Divide and Conquer

程序代写代做 CS 编程辅导

- Optimal Binary Search Trees.

- Recall that:

- The running time for a successful search in a binary search tree is proportional to the depth of the tree (i.e., the number of ancestors of the target node).
- To minimize the worst-case search time, the height of the tree should be as small as possible.
 - The ideal tree is perfectly balanced (remember AVL and red-black trees).

Recursive Backtracking + Divide and Conquer

程序代写代做 CS 编程辅导

- Optimal Binary Search Trees.

- However:

- In many BST applications, it is more important to minimize the total cost of several searches rather than the worst-case cost of a single search.
 - If x is a more frequent search target than y , we can save time by building a tree where the depth of x is smaller than the depth of y , even if that means increasing the overall depth of the tree.

Assignment Project Exam Help

Recursive Backtracking + Divide and Conquer

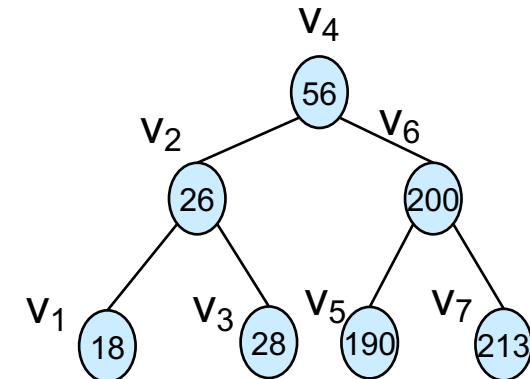

程序代写代做 CS 编程辅导

- Optimal Binary Search Trees.

- Given an array of keys $A[1 \dots n]$ and an array of corresponding access frequencies $f[1 \dots n]$. Our task is to ‘build’ the binary search tree that minimizes the total search time, assuming that there will be exactly $f[i]$ searches for each key $A[i]$.
- Let T be a BST. Let v_1, v_2, \dots, v_n be the nodes of T such that each node v_i stores the corresponding key $A[i]$.
- The total cost (ignoring constant factors) of performing all the searches is given by:

$$Cost(T, f[1..n]) := \sum_{i=1}^n f[i] \cdot \# \text{ancestors of } v_i \text{ in } T$$

<https://tutorcs.com>

$$A = [18, 26, 28, 56, 190, 200, 213]$$

Recursive Backtracking + Divide and Conquer

程序代写代做 CS 编程辅导

- Optimal Binary Search Trees.

- Now suppose v_r is the root of T .
 - v_r is an ancestor of v_i in T .
 - If $i < r$, then all ancestors of v_i in T (except the root) are in the left subtree of T .
 - If $i > r$, then all ancestors of v_i (except the root) are in the right subtree of T .

WeChat: cstutores

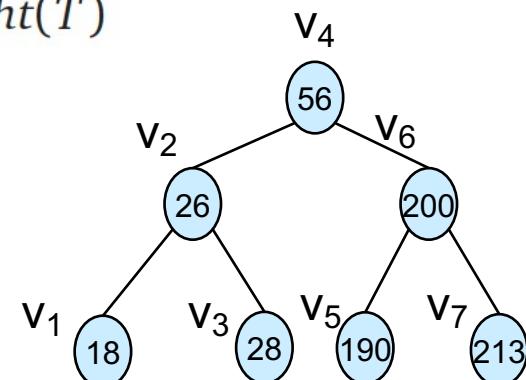

$$Cost(T, f[1..n]) = \sum_{i=1}^n f[i] + \sum_{i=1}^{r-1} f[i] \cdot \# \text{ancestors of } v_i \text{ in } \text{left}(T)$$

Assignment Project Exam Help

Email: tutorcs@163.com
+ $\sum_{i=r+1}^n f[i] \cdot \# \text{ancestors of } v_i \text{ in } \text{right}(T)$

<https://tutorcs.com>

Recursive Backtracking + Divide and Conquer

程序代写代做 CS 编程辅导

- Optimal Binary Search Trees.

- So far, we have two ways to express the cost.

$$Cost(T, f[1..n]) = \sum_{i=1}^n f[i] \cdot \# \text{ancestors of } v_i \text{ in } T$$

WeChat: cstutorcs

$$Cost(T, f[1..n]) = \sum_{i=1}^n f[i] + \sum_{i=1}^{r-1} f[i] \cdot \# \text{ancestors of } v_i \text{ in } \text{left}(T)$$

Assignment Project Exam Help
Email: tutorcs@163.com

$$+ \sum_{i=r+1}^n f[i] \cdot \# \text{ancestors of } v_i \text{ in } \text{right}(T)$$

QQ: 749389476

- Note that the second and third summations of the second equation look exactly like our first equation.

<https://tutorcs.com>

Recursive Backtracking + Divide and Conquer

程序代写代做 CS 编程辅导

- Optimal Binary Search Trees.

- Simple substitution gives recurrence for the cost.

$$\text{Cost}(T, f[1..n]) = \min_{i=1}^n \text{Cost}(left(T), f[1..r-1]) + \text{Cost}(right(T), f[r+1..n])$$

WeChat: cstutorcs

- The task now is to compute the tree T_{opt} that minimizes this cost function.

- Once we choose the correct key to store at the root, the recursion (i.e., recursive backtracking) will construct the rest of the optimal tree.
 - The left subtree $\text{left}(T_{\text{opt}})$ must be the optimal BST for the keys $A[1..r-1]$ and access frequencies $f[1..r-1]$.
 - The right subtree $\text{right}(T_{\text{opt}})$ must be the optimal BST for the keys $A[r+1..n]$ and access frequencies $f[r+1..n]$.

Recursive Backtracking + Divide and Conquer

程序代写代做 CS 编程辅导

- Optimal Binary Search Trees.

- More generally, let $OptCost(i, k)$ denote the total cost of the optimal search tree for the input frequencies $f[i..k]$.

$$OptCost(i, k) = \begin{cases} 0 & \text{if } i > k \\ \sum_{j=i}^k f[j] + \min_{i \leq r \leq k} \left\{ OptCost(i, r-1) + OptCost(r+1, k) \right\} & \text{otherwise} \end{cases}$$

Subtracting the recurrences

<https://tutorcs.com>

$$T(n) = 3T(n-1) + \alpha$$

Simplifying the recurrence

$$T(n) = O(3^n)$$

Recursion tree method (topic of next class)

Recursive Backtracking + Divide and Conquer

程序代写代做 CS 编程辅导

- The running time satisfies the recurrence:

$$T(n) = \sum_{k=1}^{n-1} (1 + T(k) + T(n-k)) + O(n)$$

$$T(n) = O(3^n)$$

- The number of binary search trees with n vertices satisfies the recurrence:

$$N(n) = \sum_{r=1}^{n-1} (N(r-1) \cdot N(n-r))$$

Recursive Backtracking + Divide and Conquer

程序代写代做 CS 编程辅导

- The running time satisfies the recurrence: $T(n) = O(3^n)$
- The number of binary search trees with n vertices satisfies the recurrence: $N(n) = \sum_{i=0}^{n-1} N(i)N(n-i-1)$
- The analysis implies:
 - Our recursive algorithm does not examine all possible BST.
 - Our algorithm saves considerable time by searching independently for the optimal left and right subtrees for each root.
 - A full enumeration of binary search trees would consider all possible pairs of left and right subtrees (hence the product in the recurrence for $N(n)$)

Divide and Conquer

程序代写代做 CS编程辅导

- Recursive in structure

- **Divide** the problem into smaller problems that are similar to the original but smaller in size
- **Conquer** the sub-problems by solving them **recursively**. If they are small enough, just solve them in a straightforward manner.
- **Combine** the solutions to create a solution to the original problem
