Hashing – Problem definition

程序代写代做 CS 编程辅导

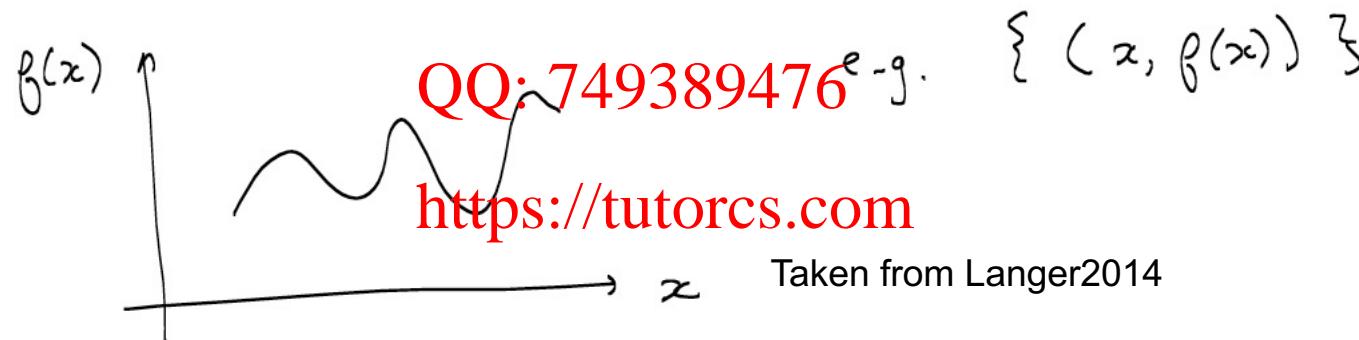

- A map is a set of (key, value) pairs. Each key maps to at most one value.

Taken from Langer2014

- This is also a map ('function' = 'map'), but we will not be considering continuous functions/maps here.

Assignment Project Exam Help
Email: tutorcs@163.com

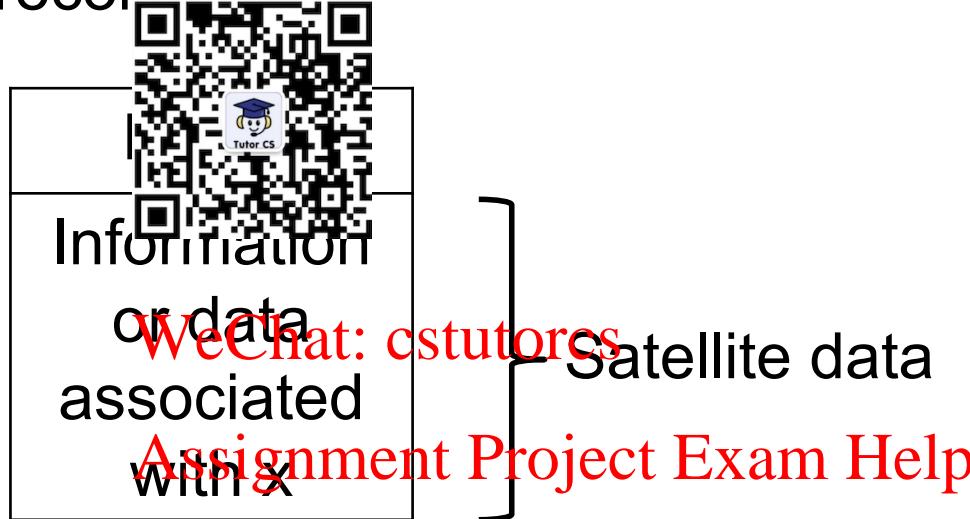

Taken from Langer2014

Hashing – Problem definition

程序代写代做 CS 编程辅导

Table S with m records x :

X

We want a data structure to store and retrieve these data.

Operations: QQ: 749389476

- $insert(S, x) : S \leftarrow S \cup \{x\}$
 - $delete(S, x) : S \leftarrow S \setminus \{x\}$
 - $search(S, k)$
- <https://tutorcs.com>
- Dynamic set

Hashing – Real world Examples

程序代写代做 CS 编程辅导

- Compilers.

- a compiler that translates code from one programming language into another. A programming language maintains a symbol table, in which the keys are identifiers and the values are arbitrary character strings corresponding to identifiers in the language.

- Password Authentication

WeChat: cstutorcs

- Keys are usernames, and values are passwords ($\text{hash}(\text{passwords})$).
- <http://www.md5.cz/> Assignment Project Exam Help

- <https://crackstation.net/hashing-security.htm>

Email: tutorcs@163.com

- Data consistency

- For example, after ~~downloading~~ [QQ: 749389476](#), you can compare the fingerprint of the downloaded file with the fingerprint of the original file. If the two fingerprints differ, the ~~files are surely different~~ <https://tutorcs.com>, if they are the same, the files are equal with a very high probability.

Hashing – Why using hash

程序代写代做 CS 编程辅导

- Hashing is an extremely effective and practical technique.
- Many applications require a dynamic set that supports only the dictionary operations
 - INSERT, SEARCH, and DELETE.
 - A hash table is an effective data structure for implementing dictionaries.
 - Under reasonable assumptions, the average time to search for an element in a hash table is O(1).
- A hash table generalizes the simpler notion of an ordinary array.
 - Directly addressing into an ordinary array makes effective use of our ability to examine an arbitrary position in an array in O(1) time.
 - The array index is computed from the key.
 - To allocate an array that has one position for every possible key.

Direct-address tables – First attempt

程序代写代做 CS 编程辅导

- Each slot, or position, corresponds to a key in U .
- If there is an element x with key k , then $T[k]$ contains a pointer to x .
- If $T[k]$ is empty, represented by Nil .
- All operations in $O(1)$, but:
 - if n (#keys) < m (#slots), lot of wasted space.
 - $|U|$ needs to be not too large (space constraint)

Hashing – Hash map

程序代写代做 CS 编程辅导

- Hash map (hash function + hash table).

- Direct addressing:

- an element with key k is stored in slot k .

- Hash function:

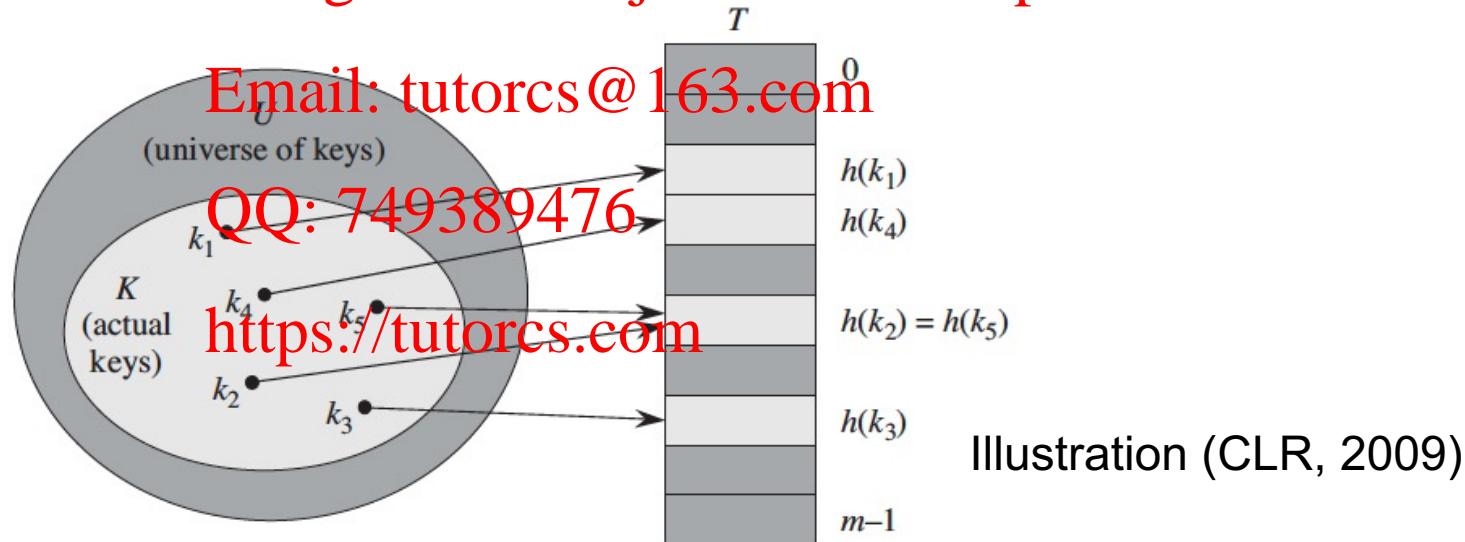

- an element with key k is stored in slot $h(k)$.

- That is, we use a hash function h to compute the slot from the key k .

- Hash function: $h : U \rightarrow \{0, 1, \dots, m-1\}$

WeChat: cstutorcs

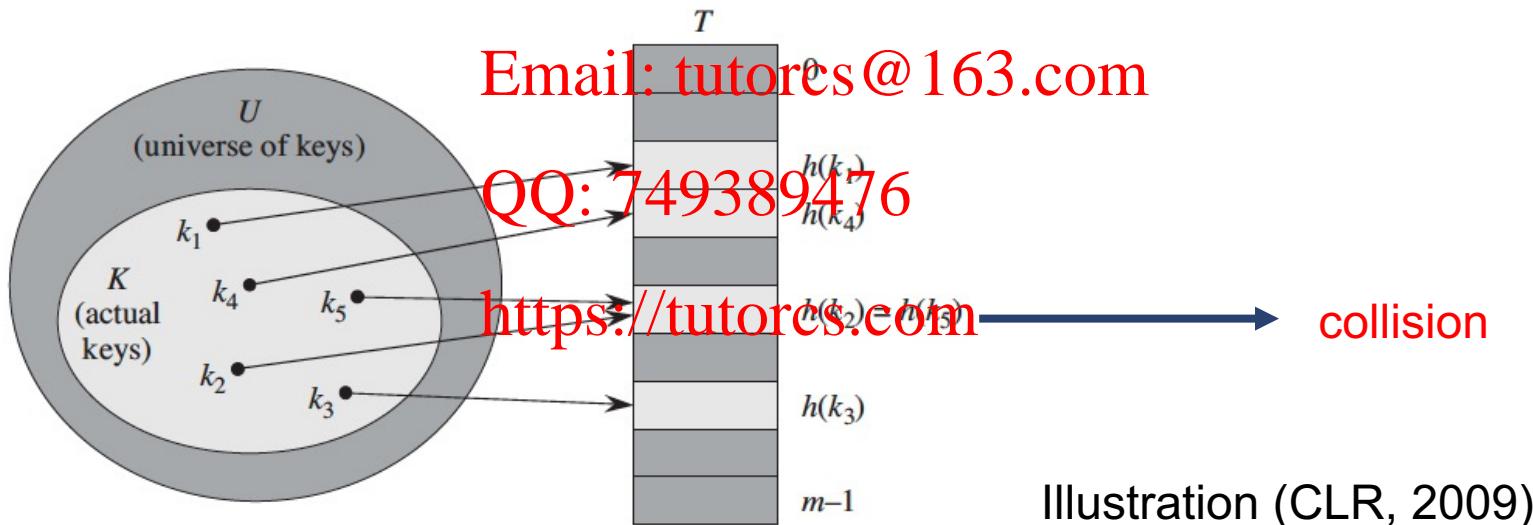

Assignment Project Exam Help

Hashing – Hash table

程序代写代做 CS 编程辅导

- The hash function reduces the range of array indices. Instead of a size of $|U|$, the array can have size m .
- The catch:** We reduce storage requirement while we maintain the benefit of searching in $O(1)$.
 - This boundary is for the average-case time, whereas for direct addressing it holds for the worst-case time.
- The hitch:** Two keys ~~may~~ hash to the same slot (i.e., collision).

QQ: 749389476

<https://tutorcs.com>

Hashing – Division Method

程序代写代做 CS 编程辅导

$$k \bmod d$$

d must be chosen carefully!

Example 1: $d = 2^r$ and all keys are even?

Odd slots are never used...

Assignment Project Exam Help

Example 2: $d = 2^r$

Email: tutorcs@163.com
 $k = 100010110101101011$

QQ: 749389476
keeps only r last bits...

$r = 2 \rightarrow 11$
 $r = 3 \rightarrow 011$
 $r = 4 \rightarrow 1011$

Good heuristic: Choose d prime not too close from a power of 2.

<https://tutorcs.com>

Note: Easy to implement, but it depends on value d

Hashing – Multiplication Method

程序代写代做 CS 编程辅导

$$h(k)$$

$$n(ks \bmod 1)$$

$$0 < A < 1$$

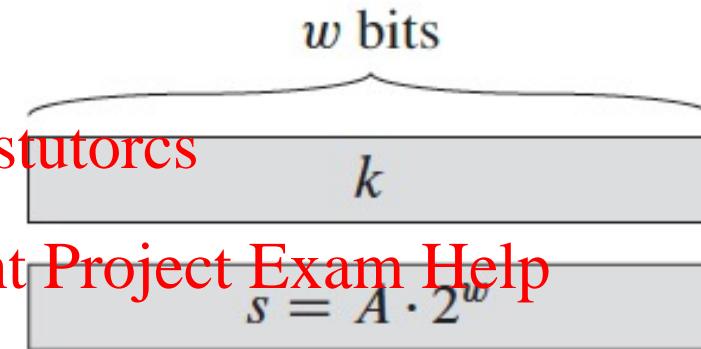

$$m = 2^p$$

$w = \text{word size computer}$

$$kA \bmod 1 = kA - [kA]$$

$$ks = 2^w r_1 + r_0 \quad (\text{2w-bit value})$$

WeChat: cstutorcs
Assignment Project Exam Help

Email: tutorcs@163.com

<https://tutorcs.com>

Illustration (CLR, 2009)

Note: A bit more complicated, but the value of m is not critical

Hashing – Universal Hashing

程序代写代做 CS 编程辅导

- A malicious adversary who has learned the hash function chooses inputs that all map to the same slot, giving worst-case behavior.

- Defeat the adversary using **Universal Hashing**

- Use a different random hash function each time.

~~WeChat: cstutorcs
Assignment Project Exam Help
Email: tutorcs@163.com
QQ: 749389476
<https://tutorcs.com>~~

- No single input will always evoke worst-case behavior.

- Ensure that the random hash function is independent of the keys that are actually going to be stored.

- Ensure that the random hash function is “good” by carefully designing a class of functions to choose from:

~~WeChat: cstutorcs
Assignment Project Exam Help
Email: tutorcs@163.com
QQ: 749389476
<https://tutorcs.com>~~

Hashing – Universal Hashing

程序代写代做 CS 编程辅导

- A finite collection of hash functions H that maps a universe U of keys to the range $\{0, 1, \dots, m-1\}$ is **universal** if:

for each pair of distinct keys $x, y \in U$,

the number of hash functions $h \in H$

for which $h(x)=h(y)$ is $\leq |H|/m$.

Assignment Project Exam Help

for a hash function h chosen randomly

from H , the chance of a collision

QQ: 749389476

between two keys is $\leq 1/m$.

<https://tutorcs.com>

Universal hash functions give good hashing behavior.

QQ: 749389476

<https://tutorcs.com>

Collision resolution – by chaining

程序代写代做 CS编程辅导

- **Insertion:** $O(1)$ time (Insert at the beginning of the list).
- **Deletion:** Search time = $O(n)$ if we use a double linked list.
- **Search:**

- Worst case: Worst search time is $O(n)$.
WeChat: cstutorcs
 - Search time = time to compute hash function + time to search the list.
Assignment Project Exam Help
 - Assuming the time to compute hash function is $O(1)$.
 - Worst time happens when all keys go the same slot (list of size n), and we need to scan the full list => $O(n)$.
Email: tutorcs@163.com
- Average case: It depends how keys are distributed among slots.
QQ: 749389476

<https://tutorcs.com>

Chaining – Average case Analysis

程序代写代做 CS 编程辅导

- Assume a **simple uniform hashing**: n keys are distributed uniformly among m

- Let n be the number of keys, and m the number of slots.

WeChat: cstutorcs

- Average number of element per linked list?

Assignment Project Exam Help

n

- Load factor: $\alpha = \frac{n}{m}$

Email: tutorcs@163.com

m

QQ: 749389476

- **Theorem:**

- The expected time of a search is $\Theta(1 + \alpha)$.

- Note: $O(1)$ if $\alpha < 1$, but $O(n)$ if α is $O(n)$.

Chaining – Average case Analysis

程序代写代做 CS 编程辅导

- **Theorem:**

- The expected time for search is $O(1 + \alpha)$.
 - expected number of elements in the chain is α defined to see whether any have a key equal to k .

- **Proof?**

WeChat: cstutorcs

Assignment Project Exam Help

- Distinguish two cases:

Email: tutorcs@163.com

- search is unsuccessful:
 - No element in the table has key k
- search is successful
 - Finding an element with key k

QQ: 749389476

<https://tutorcs.com>

Chaining – Unsuccessful search

程序代写代做 CS 编程辅导

- Assume that we can compute the hash function in $O(1)$ time.
- An unsuccessful search requires to scan all the keys in the list.
- Average search time = $O(1) + \text{average length of lists}$)
- Let n_i be the length of the list attached to slot i .
- Average value of n_i ?

WeChat: cstutorcs

Assignment Project Exam Help

$$E(n_i) = \alpha = \frac{n}{m} \quad (\text{Load factor})$$

Email: tutorcs@163.com
QQ: 749389476

$$\Rightarrow O(1) + O(\alpha) = O(1 + \alpha)$$

Chaining – Successful search

程序代写代做 CS 编程辅导

- Each list is not equally likely to be searched. Instead, the probability that a list is searched is proportional to the number of elements it contains.
- Assume the position of the searched key x is equally likely to be any of the elements stored in the list.
 - The number of elements examined during a successful search for an element x is one more than the number of elements that appear before x in x 's list.
 - new elements are placed at the front of the list, elements before x in the list were all inserted after x was inserted
 - To find the expected number of elements examined, we take the average, over the n elements x in the table, of 1 plus the expected number of elements added to x 's list after x was added to the list.

<https://tutorcs.com>

Hashing – Open Addressing

程序代写代做 CS 编程辅导

- No storage for multiple keys on single slot (i.e. no chaining).

- **Idea:** Probe the table

- Insert if the slot is empty.
- Try another hash function otherwise.

$$\bullet h: U \times \{0, \dots, m-1\} \rightarrow \{1, \dots, m\}$$

Universe of keys

WeChat: cstutorcs
Assignment Project Exam Help

- Constraints:

Email: tutorcs@163.com

- $n \leq m$ (i.e. more slots than keys to store)
- Deletion is difficult

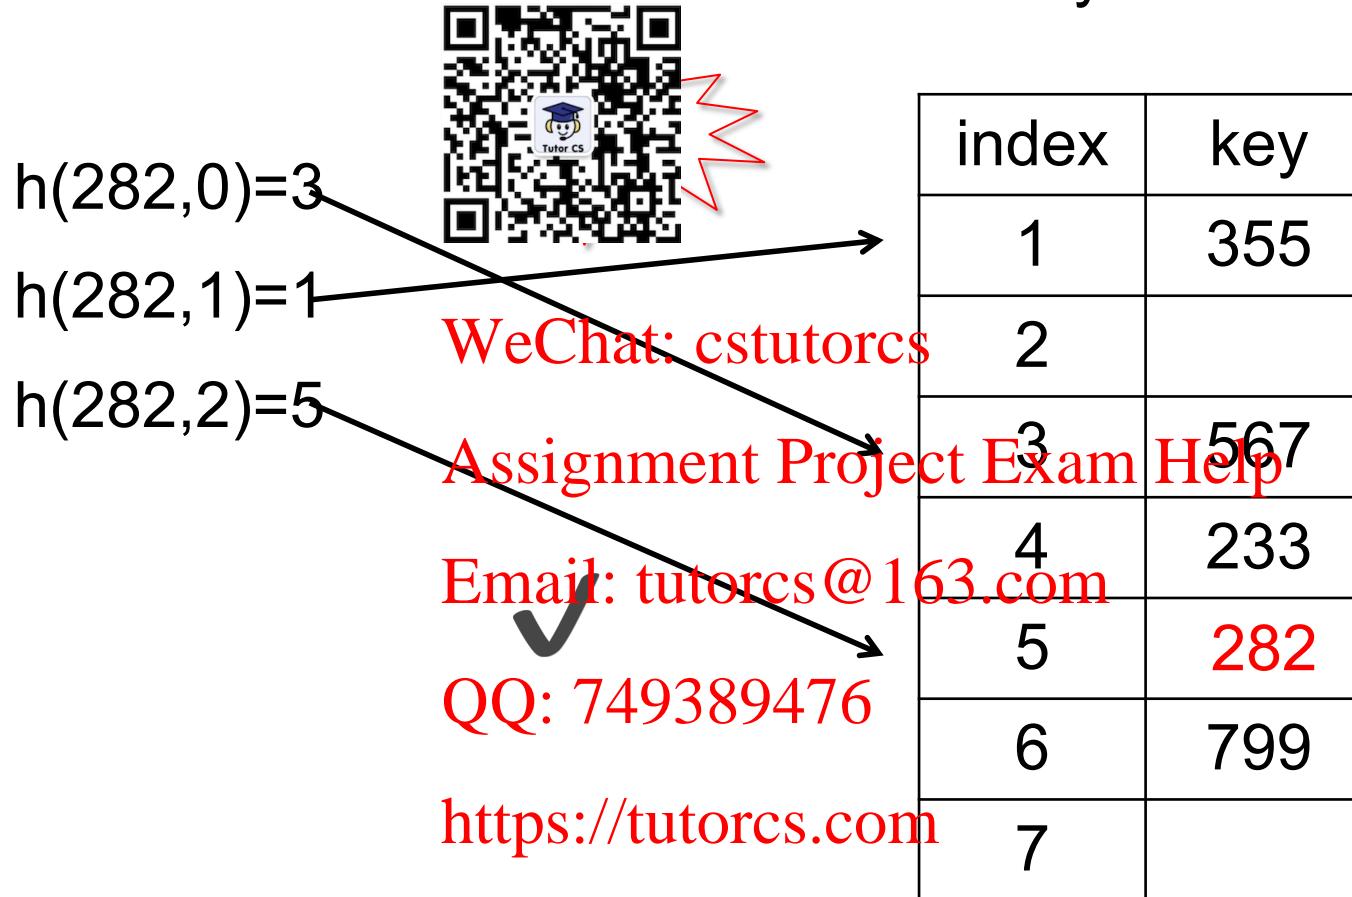

QQ: 749389476
<https://tutorcs.com>

- Challenge: How to build the hash function?

Hashing – Open Addressing

程序代写代做 CS 编程辅导

Illustration: Where to store key 282?

Note1: Search must use the same probe sequence.

Note2: The probe sequence must be a permutation of the indexes

Hashing – Open Addressing

程序代写代做 CS 编程辅导

Linear probing:

$$h(k, i) = \text{QR code} + i \bmod m$$

Notes:

- Tendency to create primary clusters (long runs of occupied slots build up).
- There are only m distinct probe sequences (the initial probe determines the entire probe sequence)

WeChat: cstutorcs

Quadratic probing: [Assignment](#) [Project](#) [Exam](#) [Help](#)

$$h(k, i) = \text{Email: tutorcs@163.com} + c_1 \cdot i + c_2 \cdot i^2 \bmod m$$

Notes:

QQ: 749389476

- The values of c_1 , c_2 and m must be constrained to ensure that we have a full permutation of $\{0, 1, \dots, m-1\}$
- There are only m distinct probe sequences
- **Secondary clustering:** If 2 distinct keys have the same h' value, then they have the same probe sequence.

Hashing – Open Addressing

程序代写代做 CS 编程辅导

Double hashing:

$$h(k, i) = \left(h_1(k) + i \cdot h_2(k) \right) \bmod m$$

- One of the best methods available.
 - More permutations.
 - Characteristics of randomly chosen permutations.
 - Alleviate the problem of clustering
- Must have $h_2(k)$ be “relatively” prime to m to guarantee that the probe sequence is a full permutation of $\{0, 1, \dots, m-1\}$.
Email: tutorcs@163.com
- Examples:
 - m power of 2 and h_2 returns odd numbers.
 - $O(m^2)$ probes are used.
 - Each possible $(h_1(k), h_2(k))$ pairs yields a distinct probe sequence.
 - m prime number and $1 < h_2(k) < m$

WeChat: cstutors

$i = 2:$
 $h(14, 2) = 1 + 2 * 4 = 9$

Hashing – Open Addressing

程序代写代做 CS 编程辅导

We assume uniform hashing: Each key equally likely to have anyone of the $n!$ permutations as its probe sequence, independently of other keys.

Theorem 1: The expected number of probes in an unsuccessful search is at most $\frac{1}{1-\alpha}$.

WeChat: tutorcs
Assignment Project Exam Help

Theorem 2: The expected number of probes in a successful search is at most $\frac{1}{\alpha} \log\left(\frac{1}{1-\alpha}\right)$

Email: tutorcs@163.com
QQ: 749389476

Reminder: $\alpha = \frac{n}{m}$ is the load factor

Open Addressing – supplemental material

程序代写代做 CS 编程辅导

Initial state: n keys are already stored in m slots.

Probability 1st slot is occupied

Probability 2nd slot is occupied given 1st is too: $(n-1)/(m-1)$.

Probability 3rd slot is occupied given 1st and 2nd is too : $(n-2)/(m-2)$.

Let X be the number of unsuccessful probes

$$\Pr\{X \geq i\} = \frac{n}{m} \cdot \frac{n-1}{m-1} \cdot \frac{n-2}{m-2} \cdots \frac{n-i+2}{m-i+2}$$

Email: tutorcs@163.com

$n < m \Rightarrow (n-j)/(m-j) \leq n/m$, for $j \geq 0$

QQ: 749389476

$$\Pr\{X \geq i\} \leq (n/m)^{i-1} = \alpha^{i-1}$$

<https://tutorcs.com>

$$E[X] = \sum_{i=1}^{\infty} \Pr\{X \geq i\} \leq \sum_{i=1}^{\infty} \alpha^{i-1} = \sum_{i=0}^{\infty} \alpha^i = \frac{1}{1-\alpha}$$

Open Addressing – home take message

程序代写代做 CS 编程辅导

Corollary

The expected number of probes to insert is at most $1/(1 - \alpha)$.

Interpretation:

- If α is constant, an unsuccessful search takes $O(1)$ time.
- If $\alpha = 0.5$, then an unsuccessful search takes an average of $1/(1 - 0.5) = 2$ probes (1.387 for a successful search).
- If $\alpha = 0.9$, takes an average of $1/(1 - 0.9) = 10$ probes (2.559 for a successful search).
